Embodying the intradisciplinary method The proposed methodology represents a qualitative and quantitative methodology. It works with the elements of the accepted typology for a detailed analysis of the signs, with the purpose of obtaining a positive, positive and neutral value for the partial design with no feedback about the evaluated category. Introduction: The approach proposed is a qualitative and quantitative methodology. It is a methodology for the evaluation and selection of the best models, which are evaluated through the obtained mean performance. The method can be applied in any field, but in this paper, in handwriting recognition, it is compared with three of the methods most used in this field: the Analyzer Method, the Configurator Method and the Transfer Method. Analyzing the literature on the subject, it was determined that there are many different typologies of descriptors for writing, which provide a huge variety of measurements of which there are few studies or no comparisons between them. The proposed methodology is a qualitative and quantitative method applied to handwriting recognition (phonetic recognition system) used in the evaluation of the models for the best automatic recognition of the signs, regardless of the implementation language. In this paper, the numerical method based on the concept of similarity (evaluated by the homology) is compared with other methods. Evaluation by similarity is a method that evaluates the partial designs by comparing it to the best model. Based on the concepts, a methodology for the quantitative evaluation of writing models in handwriting recognition was proposed. For this, the phrase "Automatic Recognition of Handwriting" was used as the theme, and the problems related to this theme were identified. It is 82157476af
